Collection, data quality and coordination

Status: Proposed work package, not a Jira assignment, client approval, or evidence of completion. Match accounts and agree the task before starting.

Shared goal and how to use this guide

The intended Sprint 1 goal is: sign in, add a supported competitor listing, request collection, and see a trustworthy observation in your own workspace. Development is planned for 28 September–11 October 2026; evaluation starts 12 October (12–18 October window). Verify course updates. No individual completion date or available hours are assumed.

First connect a page to one backend response labelled **synthetic**. This is a short learning/integration checkpoint, not the full sprint or live Amazon acceptance. Accounts, persistence, jobs and permitted source collection follow only when their dependencies are ready.

Read `docs/manual.md` sections 2–5, then the sections named below. Follow one step at a time; the later steps are a route toward the goal, not an instruction to implement the entire guide unattended. Jira owns actual status and assignments; this PDF is a dated handout.

Your deliverable and boundaries

Establish whether the intended source use is supported, define trustworthy observation meanings, and then build a small replaceable collector if its dependencies permit it. Reviewer: Hirukshanan; Ilmam reviews execution/failure behaviour. Relevant scope: PB-01/02/06/12, FR-03-06/11, NFR-02/04/05/10. Read manual sections 7–10 and the SRS source-access section.

You coordinate shared decisions, not write everyone's code. Amazon-first is selected; UK/wired mice and exact offer meaning were recommendations, not verified client decisions. No paid provider or source substitution without agreement.

First working slice: meanings and access verdict

1. Agree the synthetic observation with A/B. Explain price plus currency, missing price, unknown availability, collection time and uncertain match. Make sure nobody labels the fixture as Amazon output.
2. Read the existing source-access findings and cited official conditions. Check whether a candidate route supports retailer monitoring, history retention, sharing and required fields. Record date, references, applicable limits and evidence; never copy credentials or private delivery addresses.
3. Clarify the first marketplace, exact listing/variant, seller versus featured offer, condition and delivery context needed for a meaningful sample. Ask the client only the questions that block this decision.
4. Time-box the initial investigation to two working days after starting. Return supported, supported with limits, or blocked. A repository, API key or HTTP 200 is not permission or accuracy evidence. If unresolved, report the blocker and the concrete access/scope decision needed.

Checkpoint evidence: A reviewed observation example and dated access assessment. A well-supported blocked verdict is a completed investigation, not successful live collection. Other members continue synthetic integration.

Next slices toward the full sprint goal

1. **Adapter boundary.** Agree input/output and error meanings with B/D. Accept validated listing/context and return a candidate or classified failure. Do not write database rows or UI code in the adapter. First exercise it with controlled synthetic fixtures.
2. **Validation tests.** Cover missing price, unknown currency/stock, malformed data, variant uncertainty and seller changes where relevant. Reject or flag ambiguous identity instead of claiming a confident equivalent offer. Keep fixtures small, synthetic or permitted and sanitized.
3. **Live sample only after access passes.** Use 3–5 verified listings under the agreed context where permitted. Compare extracted values with contemporaneous manual checks and repeat under supported limits. Record successes, failures and mismatches, not only the successful requests. Do not retain source content beyond allowed terms.
4. **Failure handling.** Coordinate timeouts, allowed URLs/destinations and classified errors with D. No CAPTCHA/access-control bypass and no automatic browser/proxy workaround for denial. Limits follow the source terms; fixtures cover failures without stressing third parties.
5. **Integrate and demonstrate.** Give the candidate result to the worker, check stored/displayed fields with B/A, and trace an attempt from request to result. A worker failure preserves the previous observation and exposes failure honestly.

If live access remains blocked

Keep the live adapter and full source acceptance visibly blocked. You can still deliver the source-neutral interface, validation tests, and a clearly labelled fixture adapter after selecting that slice. Ask the client for suitable access or an explicit alternative scope; do not silently switch sources or claim completion.

Coordination and explain-back

Check that members can connect their outputs; raise shared blockers and arrange a reviewer. Rebalance work rather than becoming the only implementer. Before review, explain: What makes this observation comparable? What evidence supports use and retention? What is synthetic? Why can a seller/variant change invalidate a comparison? What remains unproven?

Review, evidence, and AI use

Before each change, explain its purpose and predict how you will check it. Implement a small change; run the check yourself; explain the result. Ask for help after a focused attempt if blocked. Never guess successful results or hide uncertainty.

Use AI as a tutor: “Read my task and the relevant manual section. Ask me to explain it. Help me plan and implement one small step, then interpret my actual check result. Do not complete the whole assignment or change shared contracts without discussion.”

For review, record: task key, what changed, why, command or walkthrough performed, actual result, limitations, material AI help, and reviewer. Use a real Jira key in your branch/PR, not the name of this guide. Done means relevant checks pass, a teammate reviews your explanation and change, and the result is integrated and demonstrated. Research tasks finish with reviewed evidence and a verdict, not invented implementation.

Stop and coordinate if an interface changes, a source requires unsupported access, a paid service is needed, or selected scope is no longer credible. Do not switch frameworks, broaden scope, or claim mock data is live. Use current repository source if this PDF is outdated.
